Fundamentals of Consensus

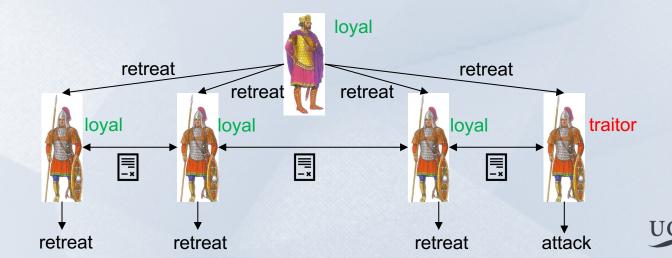

Yu Feng University of California, Santa Barbara

- Encapsulates the problem of reaching consensus.
- Introduced by Lamport et al. in 1982.
- Problem statement:
 - There are *n* generals (where *n* is fixed), one of which is the commander.
 - Some generals are *loyal*, and some of them can be *traitors* (including the commander).
 - The commander sends out an order that is either attack or retreat to each general.
 - If the commander is loyal, it sends the same order to all generals.
 - All generals take an action after some time.

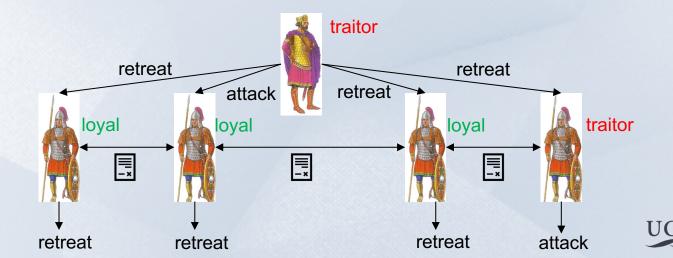

Goal:

- Agreement: No two loyal generals take different actions.
- Validity: If the commander is loyal, then all loyal generals must take the action suggested by the commander.
- Termination: All loyal generals must eventually take some action.

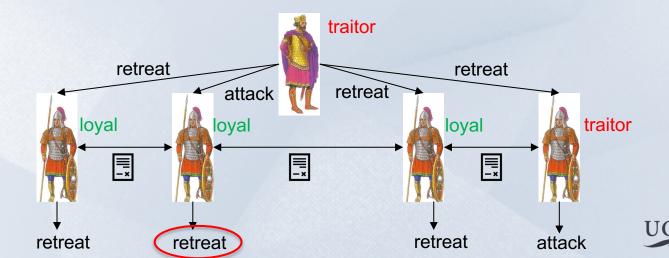

Goal:

- Agreement: No two loyal generals take different actions.
- Validity: If the commander is loyal, then all loyal generals must take the action suggested by the commander.
- Termination: All loyal generals must eventually take some action.

Goal:

- Agreement: No two loyal generals take different actions.
- Validity: If the commander is loyal, then all loyal generals must take the action suggested by the commander.
- Termination: All loyal generals must eventually take some action.

From Generals to Nodes

- Solution to the Byzantine Generals Problem is a consensus protocol.
- When modelling consensus protocols:
 - Generals → Nodes
 - Commander → Leader
 - Loyal → Honest, Traitor → Adversary
 - What can the adversarial nodes do?

Adversary

- The adversary can corrupt nodes, after which they are called adversarial.
 - Crash faults if the adversarial nodes do not send or receive any messages.
 - Omission faults if the adversarial nodes can selectively choose to drop or let through each messages sent or received.

• Byzantine faults (Byzantine adversary) if the adversarial nodes can deviate from the protocol arbitrarily.

Adversary

We typically bound the adversary's power by assuming an upper bound (f) on the number of nodes (n) that can ever be adversarial.

• e.g.
$$f < n$$
, $f < \frac{n}{2}$, $f < \frac{n}{3}$, ...

Communication

- Nodes can send messages to each other, authenticated by signatures.
- There is a public key infrastructure (PKI) setup.
 - Adversary cannot simulate honest nodes!
 - There are other ways to prevent such simulation (e.g., proof-of-work).

Consensus protocols typically assume that the adversary cannot forge signatures. Why?

Communication

We assume that the adversary *controls* the delivery of the messages subject to certain limits (the adversary runs the network):

- In a synchronous network, adversary must deliver any message sent by an honest node to its recipient(s) within Δ rounds. Here, Δ is a known bound.
- In an asynchronous network, adversary can delay any message for an arbitrary, yet finite amount of time. However, it must eventually deliver every message sent by the honest nodes.

- There are n generals (where n is fixed), one of which is the commander.
- For a public f, a subset of f generals is adversarial, and all other generals are loyal.
- The commander sends out an order that is either attack or retreat to each general.
- Network is synchronous.

Byzantine Generals Problem:

- Agreement: No two loyal generals take different actions.
- Validity: If the commander is loyal, then all loyal generals must take the action suggested by the commander.
- Termination: All loyal generals must eventually take some action.

Byzantine Broadcast (BB)

- There are n nodes (where n is fixed), one of which is the leader.
- For a public f, a subset of f nodes is adversarial, and all other nodes are honest
- The leader has an input value 0 or 1.
- Network is synchronous.

Byzantine Broadcast Problem:

- Agreement: No two honest nodes output different values.
- Validity: Leader is honest ⇒ All honest nodes output the value input to the leader.
- Termination: All honest nodes eventually output some value.

Byzantine Broadcast (BB)

- There are n nodes (where n is fixed), one of which is the leader.
- For a public f, a subset of f nodes is adversarial, and all other nodes are honest
- The leader has an input value 0 or 1.
- Network is synchronous.

Byzantine Broadcast Problem:

Agreement: No two honest nodes output different values.

even when the leader is adversarial!!

- Validity: Leader is honest ⇒ All honest nodes output the value input to the leader.
- Termination: All honest nodes eventually output some value.

Byzantine Broadcast (BB)

- There are n nodes (where n is fixed), one of which is the leader.
- For a public f, a subset of f nodes is adversarial, and all other nodes are honest
- The leader has an input value 0 or 1.
- Network is synchronous.

Byzantine Broadcast Problem:

No double spend

Agreement: No two honest nodes output different values.

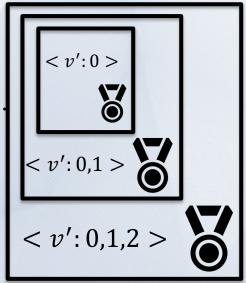

even when the leader is adversarial!!

- Validity: Leader is honest ⇒ All honest nodes output the value input to the leader.
- Termination: All honest nodes eventually output some value.

No censorship

Protocol for BB: Setup

- Denote the nodes by the indices i = 0, 1, 2, ..., n.
- Node 0 is the leader. Let v denote its value.
- Let V_i denote the set of values received by node i.
- Time moves in *lock-step*.

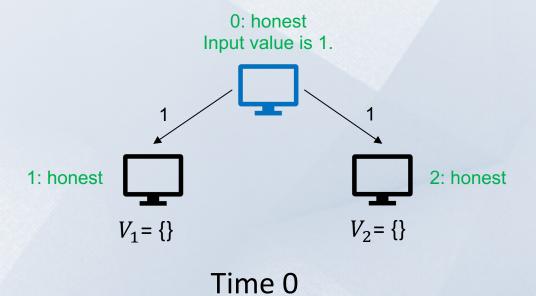

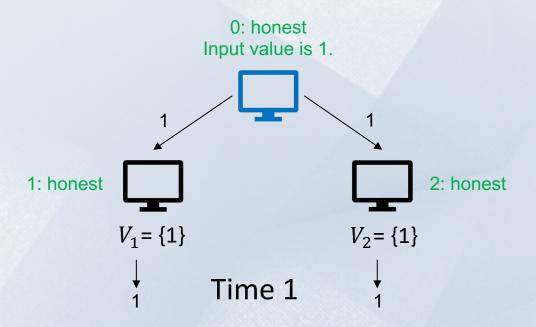

- Let $\langle v' : i \rangle$ denote the value v' signed by node i.
- Let $\langle v': i, j, ..., l, k \rangle$ denote a signature chain signed by i, j, ..., k:
 - Recursive definition: $\langle v': i, j, ..., l, k \rangle = \langle \langle v': i, j, ..., l \rangle : k \rangle$

- Time 1: (the broadcast value)
 - Node *i*:
 - Upon receiving any < v': 0 >, add v' to V_i .
 - Decide value choice(V_i).

choice(V_i):

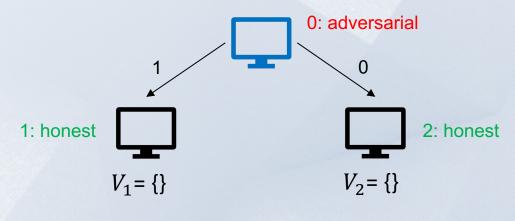

- If $V_i = \{v\}$, return v.
- Else, return 0.

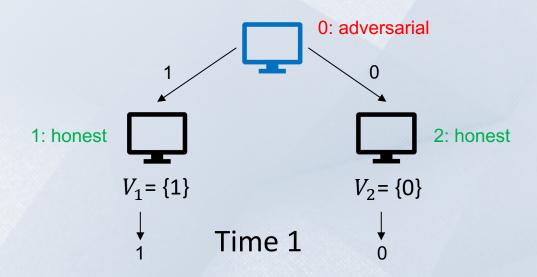

Validity is satisfied!

Problem: what if the leader is adversarial?

Time 0

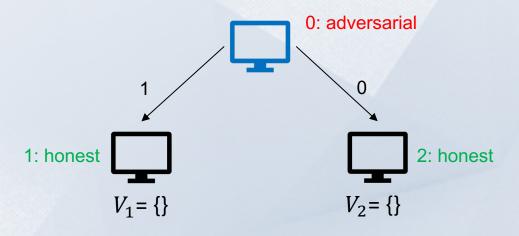

Problem: what if the leader is adversarial?

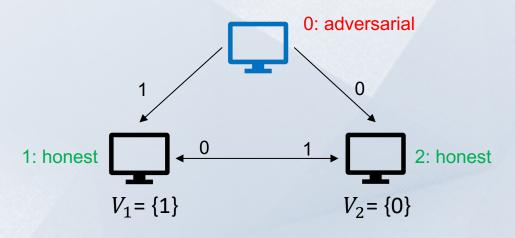

Agreement is violated!

- Time 0: Leader broadcasts $\langle v: 0 \rangle$.
- Time 1:
 - Node *i*:
 - Upon receiving any < v': 0 >, add v' to V_i , and broadcast < v': 0, i >.
- Time 2:
 - Node i:
 - Upon receiving any $\langle v': 0, j \rangle$, where $j \neq 0$, add v' to V_i .
 - Decide value choice(V_i).

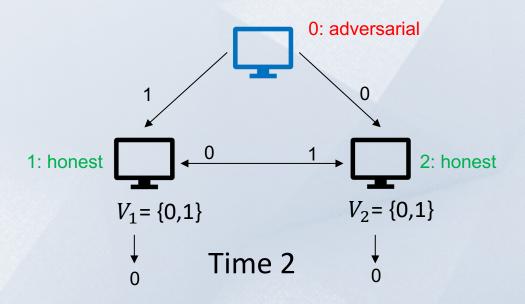

// v is either 0 or 1. (the broadcast value)

Time 0

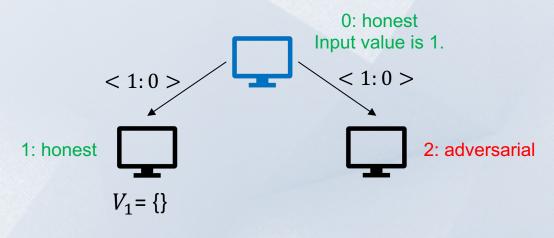

Time 1

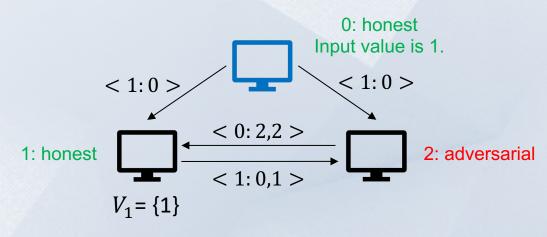

Agreement is satisfied!

Problem: what if one of the nodes is adversarial?

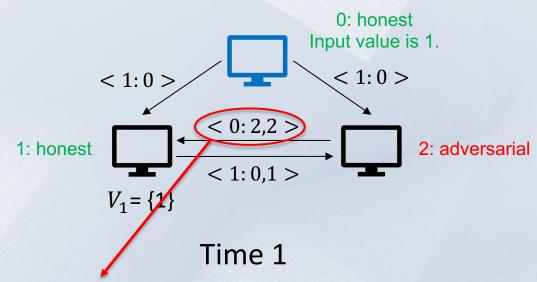

Time 0

Problem: what if one of the nodes is adversarial?

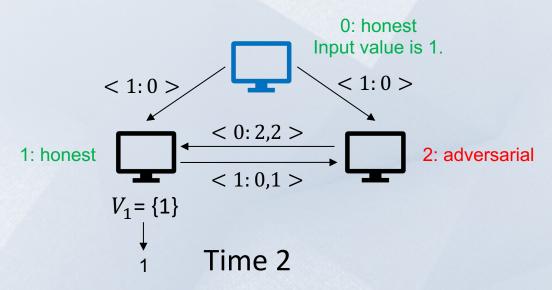

Time 1

Problem: what if one of the nodes is adversarial?

Invalid since the first signature is not by the leader, i.e., node 0. Thus, 0 is not added to V_1 .

Problem: what if one of the nodes is adversarial?

Validity is satisfied as well!

So are agreement and termination!

Dolev-Strong (1983)

- - Node *i*:
 - Upon receiving any $< v': 0, i_1 \dots, i_{t-1} >$, where $i \neq i_1 \neq \dots \neq i_{t-1}$ and $v' \notin V_i$, add v' to V_i and broadcast $< v': 0, i_1 \dots, i_{t-1}, i >$.
- Time f + 1:
 - Node i:
 - Upon receiving any $< v': 0, i_1 ..., i_f >$, where $i \neq i_1 \neq \cdots \neq i_f$ and $v' \notin V_i$, add v' to V_i .
 - Decide value choice(V_i).

Security of Dolev-Strong (1983)

Theorem (Dolev-Strong, 1983): For any f < n, Dolev-Strong (1983) with n nodes and f + 1 rounds satisfies agreement, validity and termination in a synchronous network.

(try to prove yourself ... the proof is in the slides at the end of the deck)

Converse Theorem: Any (deterministic) protocol that satisfies agreement, validity and termination for n nodes in a synchronous network with resilience up to f crash (as well as Byzantine) faults must have an execution with at least f+1 rounds.

A Centralized Bank

Blockchain (State Machine Replication)

Log (Ledger): an ever-growing, linearly-ordered *sequence* of transactions.

$$tx_2tx_1tx_4...$$

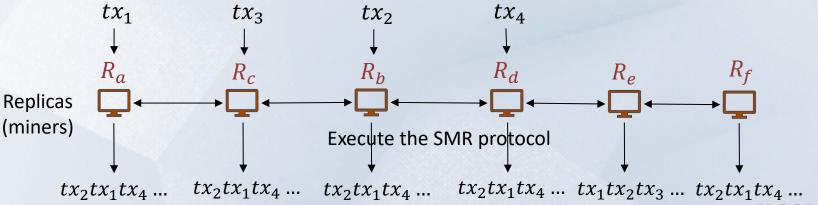

$$tx_2tx_1tx_4 \dots$$

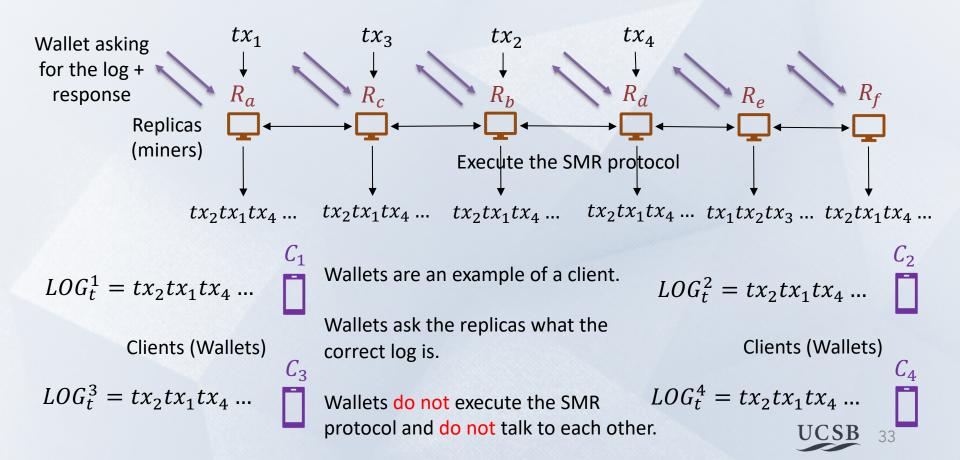

$$tx_2tx_1tx_4 \dots$$

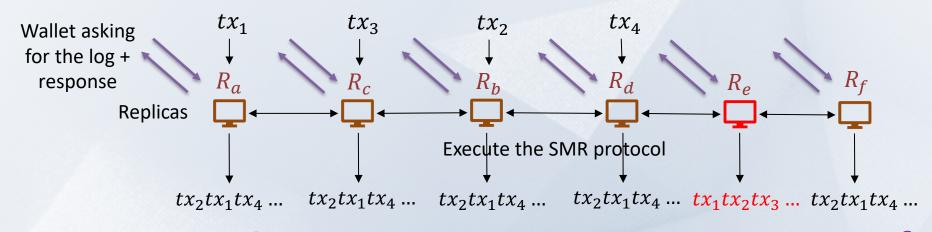

Two parties of SMR:

- Replicas receive transactions, execute the SMR protocol and determine the log.
- Clients are the learners: They communicate with the replicas to learn the log.

Goal of SMR is to ensure that the clients learn the same log.

$$LOG_t^1 = tx_2tx_1tx_4 \dots$$

Clients (Wallets)

$$LOG_t^3 = tx_2tx_1tx_4 \dots$$

How does a wallet learn the correct log from the replicas?

- It <u>asks the replicas</u> what the correct log is.
- Wallet then accepts the answer given by <u>majority</u> of the replicas as its log.

Wallet learns the correct log if over half of the replicas are honest!

$$LOG_t^2 = tx_2 tx_1 tx_4 \dots$$

Clients (Wallets)

$$LOG_t^4 = tx_2 tx_1 tx_4 \dots$$

Security for SMR: Definitions

Concatenation (A||B):

• Suppose we have sequences $A = tx_1tx_2$ and $B = tx_3tx_4$. What is $A||B| = tx_1tx_2tx_3tx_4$

Prefix relation ($A \leq B$): Sequence A is said to be a prefix of sequence B, if there exists a sequence C (that is potentially empty) such that B = A || C.

Suppose we have $A = tx_1tx_2tx_3tx_4$, $B = tx_1tx_2tx_3$ and $D = tx_1tx_2tx_4$.

- Is B a prefix of A?
 - Yes
- Is D a prefix of A?
 - No

Security for SMR: Definitions

Two sequences A and B are consistent if either $A \leq B$ is true or $B \leq A$ is true or both statements are true.

Are these two logs consistent: $LOG^{Alice} = tx_1tx_2tx_3tx_4$, $LOG^{Bob} = tx_1tx_2tx_3$?

Yes!

What about $LOG^{Alice} = tx_1tx_2tx_3$, $LOG^{Bob} = tx_1tx_2tx_3tx_4$?

Yes!

What about $LOG^{Alice} = tx_1tx_2$, $LOG^{Bob} = tx_1tx_3$?

No!

Security for SMR

Let LOG_t^i denote the log outputted by a client i at time t. Then, a **secure** SMR protocol satisfies the following guarantees:

Safety (Consistency): Similar to agreement!

• For any two clients i and j, and times t and s: either $LOG_t^i \leq LOG_s^j$ is true or $LOG_s^j \leq LOG_t^i$ is true or both (Logs are consistent).

Liveness: Similar to validity and termination!

• If a transaction tx is input to an honest replica at some time t, then for all clients i, and times $s \ge t + T_{conf}$: $tx \in LOG_s^i$.

Security for SMR

Let LOG_t^i denote the log outputted by a client i at time t. Then, a **secure** SMR protocol satisfies the following guarantees:

Safety (Consistency): Similar to agreement!

• For any two clients i and j, and times t and s: either $LOG_t^i \leq LOG_s^j$ is true or $LOG_s^j \leq LOG_t^i$ is true or both (Logs are consistent).

Liveness: Similar to validity and termination!

• If a transaction tx is input to an honest replica at some time t, then for all clients i, and times $s \ge t + T_{conf}$: $tx \in LOC^i$

spend

Why is safety important?

Suppose Eve has a UTXO.

- tx_1 : transaction spending Eve's UTXO to pay to car vendor Alice.
- tx_2 : transaction spending Eve's UTXO to pay to car vendor Bob.

Alice's ledger at time t_1 contains tx_1 :

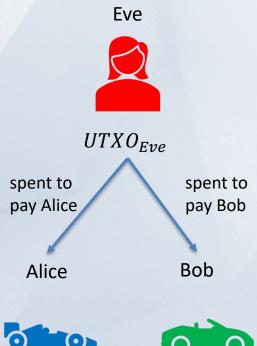

$$LOG_{t_1}^{Alice} = \langle tx_1 \rangle$$

Alice thinks it received Eve's payment and sends over the car.

Bob's ledger at time t_2 contains tx_2 :

$$LOG_{t_2}^{Bob} = < tx_2 >$$

Bob thinks it received Eve's payment and sends over the car.

Why is safety important?

Suppose Eve has a UTXO.

- tx_1 : transaction spending Eve's UTXO to pay to car vendor Alice.
- tx_2 : transaction spending Eve's UTXO to pay to car vendor Bob.

Alice's ledger at time t₁
 contains tx₁:

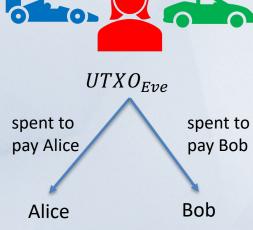

$$LOG_{t_1}^{Alice} = < tx_1 >$$

 Alice thinks it received Eve's payment and sends over the car. • Bob's ledger at time t_2

 $LOG_{t_2}^{Bob} = < tx_2 >$

contains tx_2

 Bob thinks it received Eve's payment and sends over the car.

Eve

When safety is violated, Eve can double-spend!

SMR vs. Byzantine Broadcast

- Single shot vs. Multi-shot
 - **Broadcast** is single shot consensus. Each node outputs a single value.
 - State Machine Replication is multi-shot. Each client continuously outputs a log, which is a sequence of transactions (values).
- Who are the learners?
 - In **Broadcast**, the nodes executing the protocol are the same as the nodes that output decision values.
 - In State Machine Replication, protocol is executed by the replicas, whereas the goal is for the clients to learn the log.
 - · Replicas must ensure that the clients learn the same log.

Building an SMR protocol

Security Proof for Dolev-Strong (1983)

Proof: We prove that Dolev-Strong satisfies termination, validity and agreement.

Termination: Protocol terminates in n + 1 time.

Validity: An honest leader signs only one value, namely its value v. It is received by all honest nodes at time 1 and the only signature chain that can exist are those with the value v.

Security Proof for Dolev-Strong (1983)

Agreement: Suppose an honest node i added some value v' to V_i at some time $t \le n$. Then, node i must have received a length t signature chain on v', i.e., $\langle v' : 0, i_1 ..., i_{t-1} \rangle$, at time t. Now,

- If $t \le n-1$, node i will broadcast v' with a length t+1 signature chain.
- If t=n, there must be a signature by an honest node among the n-1 nodes $i_1\ldots,i_{n-1}$, (e.g., i_j) that broadcast v' with length $j\leq n-1$ signature chain.

In either case, all honest nodes add v' to V_i latest at time n, i.e., before termination.

Finally, any value added by an honest node by termination is added by all other honest nodes by termination, i.e., $V_i = V_j$ for all honest nodes i, j.
